Pearson

The Pearson's correlation coefficient ( $r$ ) is a measure of linear correlation between two variables. It's value lies between -1 and +1, -1 indicating total negative linear correlation, 0 indicating no linear correlation and 1 indicating total positive linear correlation. Furthermore,  $r$  is invariant under separate changes in location and scale of the two variables, implying that for a linear function the angle to the x-axis does not affect  $r$ . To calculate  $r$  for two variables  $X$  and  $Y$ , one divides the covariance of  $X$  and  $Y$  by the product of their standard deviations.

Spearman

The Spearman's rank correlation coefficient ( $\rho$ ) is a measure of monotonic correlation between two variables, and is therefore better in catching nonlinear monotonic correlations than Pearson's  $r$ . It's value lies between -1 and +1, -1 indicating total negative monotonic correlation, 0 indicating no monotonic correlation and 1 indicating total positive monotonic correlation. To calculate  $\rho$  for two variables  $X$  and  $Y$ , one divides the covariance of the rank variables of  $X$  and  $Y$  by the product of their standard deviations.

Kendell

Similarly to Spearman's rank correlation coefficient, the Kendall rank correlation coefficient ( $\tau$ ) measures ordinal association between two variables. It's value lies between -1 and +1, -1 indicating total negative correlation, 0 indicating no correlation and 1 indicating total positive correlation. To calculate  $\tau$  for two variables  $X$  and  $Y$ , one determines the number of concordant and discordant pairs of observations.  $\tau$  is given by the number of concordant pairs minus the discordant pairs divided by
